## Sequence To Sequence（Seq2seq）

－Machine translation as directly learning a function mapping from source sequence to target sequence
target：
The weather is nice

Source：天 气 Decoder：LSTM很 好

Sutskever et al．Sequence to Sequence Learning with Neural Networks． 2014

## Sequence To Sequence（Seq2seq）

－Machine translation as directly learning a function mapping from source sequence to target sequence
target：
The weather is nice

$$
P(Y \mid X)=\prod P\left(y_{t} \mid y_{<t}, x\right)
$$

Training loss：Cross－Entropy

$$
l=-\sum_{n} \sum_{t} \log f_{\theta}\left(x_{n}, y_{n, 1}, \ldots, y_{n, t-1}\right)
$$

Teacher－forcing during training．
（pretend to know groundtruth for prefix）

Sutskever et al．Sequence to Sequence Learning with Neural Networks． 2014

## Stacked LSTM for seq-2-seq

- More layers of LSTM

## Limitation of RNN/LSTM

- No full context (only oneside)
- Bidirectional LSTM encoder could alleviate
- But still no long context
- Sequential computation in nature (encoder)
- not possible to parallelize the computation
- Vanishing gradient

## Motivation for New Network Architecture

－Full context and parallel：use Attention in both encoder and decoder
－no recurrent
target：
I like singing and dancing．

Source：我喜欢唱歌和跳舞。

## Attention

## Each output token depends on input tokens differently

A context vector c represents the related

$\mathrm{X}_{1} \mathrm{X}_{2} \mathrm{X}_{3} \mathrm{X}_{4} \mathrm{X}_{5}$ source context for current predicting word.
$\alpha_{m j}=\operatorname{Softmax}\left(D\left(g_{m}, h_{1 \ldots n}\right)\right)=\frac{\exp \left(D\left(g_{m}, h_{j}\right)\right)}{\sum_{k} \exp \left(D\left(g_{m}, h_{k}\right)\right.}$
$c_{m}=\sum_{j} \alpha_{m j} h_{j}$
$D\left(g_{m}, h_{j}\right)=g_{m} \cdot h_{j}$
The probability of word $y \_i$ is computed as:
$p\left(y_{m}\right)=\operatorname{Softmax}\left(W \cdot\left[\begin{array}{l}g_{m} \\ c_{m}\end{array}\right]+b\right)$

## Transformer

## Encoder

我喜欢唱歌和跳舞。

## Decoder

## How Does Transformer Translate?

## Transformer Multi-head Attention

- C layers of encoder (=6)
- D layers of decoder (=6)

## MultiHead Attention And Feed Forward Network

## Scaled Dot-Product Attention

## Attention $(Q, K, V)=\operatorname{Softmax}\left(\frac{Q K^{T}}{\sqrt{d}}\right) V$

## Multi-head Attention

- Instead of one vector for each token
- break into multiple heads
- each head perform attention
$\operatorname{Head}_{i}=\operatorname{Attention}\left(Q W_{i}^{Q}, K W_{i}^{K}, V W_{i}^{V}\right)$
$\operatorname{MultiHead}(Q, K, V)=\operatorname{Concat}\left(\right.$ Head $_{1}$, Head $_{2}, \ldots$, Head $\left._{h}\right) W^{o}$

## Self-Attention for Decoder

- Maskout right side before softmax (-inf)

Scaled Dot-Product

## Feedforward Net

- $\operatorname{FFN}(x)=\max \left(0, x \cdot W_{1}+b_{1}\right) \cdot W_{2}+b_{2}$
- internal dimension size $=2048$ (in Vaswani 2017)

## Residual Connection and Layer Normalization

- Residual Connection
- Make it zero mean and unit variance within layer
- Post-norm
- Pre-norm

## Embedding

- Token Embedding: 512 (base), 1024 (large)
- Shared (tied) input and output embedding
- Positional Embedding:
- to distinguish words in different position, Map position labels to embedding, dimension is same as Tok Emb

$$
\begin{aligned}
& P E_{p o s, 2 i}=\sin \left(\frac{p o s}{1000^{2 i / d}}\right) \\
& P E_{p o s, 2 i+1}=\cos \left(\frac{p o s}{1000^{2 i / d}}\right)
\end{aligned}
$$

## Transformer

## Encoder

我喜欢唱歌和跳舞。

## Decoder

## Training Loss

$P(Y \mid X)=\prod P\left(y_{t} \mid y_{<t}, x\right)$
Training loss：Cross－Entropy
$l=-\sum_{n} \sum_{t} \log f_{\theta}\left(x_{n}, y_{n, 1}, \ldots, y_{n, t-1}\right)$
Teacher－forcing during training．
（pretend to know groundtruth for prefix）
target：
I like singing and dancing．

Source：我喜欢唱歌和跳舞。

## Training

- Dropout
- Applied to before residual
- and to embedding, pos emb.
- p=0.1~0.3
- Label smoothing
- 0.1 probability assigned to non-truth
- Vocabulary:
- En-De: 37K using BPE
- En-Fr: 32k word-piece (similar to BPE)

## Label Smoothing

- Assume $\mathbf{y} \in \mathbb{R}^{n}$ is the one-hot encoding of label

$$
y_{i}= \begin{cases}1 & \text { if belongs to class } i \\ 0 & \text { otherwise }\end{cases}
$$

- Approximating $0 / 1$ values with softmax is hard
- The smoothed version

$$
y_{i}= \begin{cases}1-\epsilon & \text { if belongs to class } i \\ \epsilon /(n-1) & \text { otherwise }\end{cases}
$$

- Commonly use $\epsilon=0.1$

## Training

- Batch
- group by approximate sentence length
- still need shuffling
- Hardware
- one machine with 8 GPUs (in 2017 paper)
- base model: 100k steps (12 hours)
- large model: 300k steps (3.5 days)
- Adam Optimizer
- increase learning rate during warmup, then decrease
$\eta=\frac{1}{\sqrt{d}} \min \left(\frac{1}{\sqrt{t}}, \frac{t}{\sqrt{t_{0}^{3}}}\right)$

## ADAM

$$
\begin{aligned}
& m_{t+1}=\beta_{1} m_{t}-\left(1-\beta_{1}\right) \nabla \ell\left(x_{t}\right) \\
& v_{t+1}=\beta_{2} v_{t}+\left(1-\beta_{2}\right)\left(\nabla \ell\left(x_{t}\right)\right)^{2} \\
& \hat{m}_{t+1}=\frac{m_{t+1}}{1-\beta_{1}^{t+1}} \\
& \hat{v}_{t+1}=\frac{v_{t+1}}{1-\beta_{2}^{t+1}} \\
& x_{t+1}=x_{t}-\frac{\eta}{\sqrt{\hat{v}_{t+1}}+\epsilon} \hat{m}_{t+1}
\end{aligned}
$$

## Model Average

- A single model obtained by averaging the last 5 checkpoints, which were written at 10-minute interval (base)
- decoding length: within source length +50

## Quiz

- https://edstem.org/us/courses/31035/ lessons/57196/slides/321725

## Sequence Decoding

## Autoregressive Generation

greedy decoding: output the token with max next token prob

But, this is not necessary the best

## Inference

- Now already trained a model $\theta$
- Decoding/Generation: Given an input sentence x, to generate the target sentence $y$ that maximize the probability $P(y \mid x ; \theta)$
. $\operatorname{argmax} P(y \mid x)=f_{\theta}(x, y)$
$y$
- Two types of error
- the most probable translation is bad $\rightarrow$ fix the model
- search does not find the most probably translation $\rightarrow$ fix the search
- Most probable translation is not necessary the highest BLEU one!

## Decoding

- $\operatorname{argmax} P(y \mid x)=f_{\theta}(x, y)$ $y$
- naive solution: exhaustive search
- too expensive
- Beam search
- (approximate) dynamic programming

## Beam Search

- start with empty S
- at each step, keep k best partial sequences
- expand them with one more forward generation
- collect new partial results and keep top-k

## Beam Search (pseudocode)

```
best_scores = []
add {[0], 0.0} to best_scores # 0 is for beginning of sentence token
for i in 1 to max_length:
    new_seqs = PriorityQueue()
    for (candidate, s) in best_scores:
        if candidate[-1] is EOS:
                prob = all -inf
                prob[EOS] = 0
            else:
            prob = using model to take candidate and compute next token
probabilities (logp)
    pick top k scores from prob, and their index
    for each score, index in the top-k of prob:
        new_candidate = candidate.append(index)
    new_score = s + score
    if not new_seqs.full():
```

## Deep Transformer

- 30 ~ 60 encoder
- 12 decoder
- dynamic linear combination of layers (DLCL)
- or. deeply supervised
- combine output from all layers

Wang et al. Learning Deep Transformer Models for Machine Translation, 2019.

Wang et al. Learning Deep Transformer Models for Machine Translation, 2019.

## Hot Topics in MT

- Parallel Decoding (e.g. NAT, GLAT, DAT,...)
- Low-resource MT
- Unsupervised MT
- Multilingual NMT, Zero-shot NMT
- Speech-to-text translation
- (Offline) ST
- Streaming ST

## Summary

- Key components in Transformer
- Positional Embedding (to distinguish tokens at different pos)
- Multihead attention
- Residual connection
- layer norm
- Transformer is effective for machine translation, and many other tasks

## Next Up

- Pretraining for NLP
- BERT
- GPT, ChatGPT
